October 14, 2013

Abstract

A multivariate stochastic volatility model with the dynamic correlation and the cross leverage effect is described and its efficient estimation method using Markov chain Monte Carlo is proposed. The time-varying covariance matrices are guaranteed to be positive definite by using a matrix exponential transformation. Of particular interest is our approach for sampling a set of latent matrix logarithm variables from their conditional posterior distribution, where we construct the proposal density based on an approximating linear Gaussian state space model. The proposed model and its extended models with fat-tailed error distribution are applied to trivariate returns data (daily stocks, bonds, and exchange rates) of Japan. Further, a model comparison is conducted including constant correlation multivariate stochastic volatility models with leverage.

Key words: Dynamic correlation, Leverage effect, Matrix exponential, Markov chain Monte Carlo, Multi-move sampler, Multivariate stochastic volatility

1 Introduction

Over the last several decades, there has been a great deal of interest in modeling volatilities of multivariate stock market returns. The examples are multivariate generalized autoregressive conditional heteroskedasticity (GARCH) models (see the review of Bauwens, Laurent, and Rombouts (2006)), multivariate stochastic volatility (SV) models (see the review of Asai, McAleer, and Yu (2006), Chib, Omori, and Asai (2009)) and realized covariance models (e.g. Andersen, Bollerslev, Diebold, and Ebens (2001), Barndorff-Nielsen and Shephard (2004), Chiriac and Voev (2010), Audrino and Corsi (2010), Voev (2007), Bauer and Vorkink (2010), Jin and Maheu (2010) and Sheppard (2007)). The realized covariance model uses the high-frequency data to estimate covariance matrices and regard them as observed covariance matrices, while they are latent variables in GARCH and SV models.

Various multivariate volatility models have been proposed in the literature to describe the dynamic properties of the covariance matrices such as the volatility clustering, the dynamic correlations, and the leverage effects. The DCC models, (Engle (2002)) and BEKK model (Engle and Kroner (1995)) are such multivariate GARCH models, and autoregressive Wishart models (Philipov and Glickman (2006) and Gourieroux, Jasiak, and Sufana (2009)) are examples in multivariate SV models. The common difficulty in these models is to keep the covariance matrices positive definite. To overcome this difficulty, reparameterization methods are considered in Yu and Meyer (2006), Tsay (2005), and Jungbacker and Koopman (2006). The Choleski decomposition of the covariance matrix is also considered in Lopes, McCulloch, and Tsay (2012).

However, there have been still few previous works on the multivariate volatility models with both dynamic correlations and cross leverage effects. Cross leverage refers to the correlation between the $i$-th asset return at time $t$ and the function of $j$-th asset volatility at time $t+1$ (when $i = j$, we simply call it a leverage effect). Thus, to model these properties of covariance matrices, this paper considers the matrix logarithm transformation which is known useful to model positive definite matrices in a flexible way. Since the seminal work of Chiu, Leonard, and Tsui (1996), the matrix exponential model for the covariance matrix has been applied to the spatial model to simplify the calculation of log-likelihood functions (LeSage and Pace (2007)), and is extended to the GARCH model (Kawakatsu (2006)), the SV model (Asai, McAleer, and Yu (2006)) and the realized covariation model (Bauer and Vorkink (2010) and Sheppard (2007)) for multivariate financial time series.

We consider the general multivariate volatility model using the matrix exponential SV
model with cross leverage effects and propose an efficient computational algorithm. This is a generalization of Ishihara and Omori (2012) who propose the following multivariate stochastic volatility (MSV) model with cross-asset leverage effect of the form

\[ y_t = \text{diag}(\exp(\alpha_{1t}/2), \ldots, \exp(\alpha_{pt}/2)) \varepsilon_t, \quad (1) \]

\[ \alpha_{t+1} = \Phi \alpha_t + \eta_t, \quad (2) \]

\[ (\varepsilon_t', \eta_t')' \sim N_{2p}(0, \Sigma), \quad (3) \]

where \( y_t = (y_{1t}, \ldots, y_{pt})', \ \alpha_t = (\alpha_{1t}, \ldots, \alpha_{pt})', \ \Phi = \text{diag}(\phi_1, \ldots, \phi_p) \) and \( N_p(\mu, \Sigma) \) denotes the \( p \)-dimensional normal distribution with mean \( \mu \) and variance \( \Sigma \). This is fairly general in the sense that there is no restriction imposed on the covariance matrix \( \Sigma \), while, in the previous literature, various parameter restrictions are imposed (e.g. Asai and McAleer (2006), Asai and McAleer (2009), Chan, Kohn, and Kirby (2006), and Danielsson (1998)) to estimate parameters based on the Monte Carlo likelihood. We, further, model the dynamic covariance matrices (dynamic variances and correlations) using a matrix logarithm transformation. Since it is difficult to implement a maximum likelihood estimation for our proposed model without imposing restrictions on parameters, we take Bayesian approach and estimate posterior distributions of model parameters using Markov chain Monte Carlo (MCMC) method. The simple sampling algorithm for the latent covariance matrices is known to be inefficient as discussed in Ishihara and Omori (2012). They showed that the single-move sampler which samples one volatility variable given others is highly inefficient and proposed the efficient multi-move sampler (block sampler) which divides the vector of all latent variables into blocks and samples one block given other blocks based on Omori and Watanabe (2008). Thus we construct the multi-move sampler for our matrix exponential model and show that it is efficient in comparison with the alternative simple sampling algorithm.

The rest of the paper is organized as follows. In Section 2, we introduce an matrix exponential stochastic volatility model with cross leverage effects. Bayesian estimation method and the associated particle filter for calculating likelihood functions are described in Section 3. Section 4 shows the efficiency of our proposed algorithm using the simulated data, and, in Section 5, the empirical studies are given using the trivariate asset returns data (stock indices, bond indices and foreign exchange rates). We conduct a model selection among the proposed model, extended models with fat-tailed error distribution and some constant correlation multivariate SV models. Section 6 concludes the paper.
2 Matrix exponential stochastic volatility

This section proposes the matrix exponential stochastic volatility (MESV) model with cross leverage effects. The MESV model is based on the matrix exponential transformation as below. A matrix exponential is widely studied in the context of multidimensional differential equations and Lie algebra. The statistical applications of the matrix exponential transformation are given, for example, in Chiu, Leonard, and Tsui (1996), and Kawakatsu (2006). For any \( p \times p \) matrix \( A \), the matrix exponential is defined by the following power series expansion

\[
\exp(A) = \sum_{s=0}^{\infty} \frac{1}{s!} A^s,
\]

where the series converges absolutely if all eigenvalues of \( A \) are finite. (see e.g. Abadir and Magnus (2005) for various properties of the matrix exponential transformation). For any real symmetric positive definite matrix \( C \), there exists a real symmetric \( p \times p \) matrix \( A \) such that \( C = \exp(A) \), and the matrix \( A \) is obtained by the matrix logarithm transformation. Conversely, for any real symmetric matrix \( A \), \( C = \exp(A) \) is a symmetric positive definite matrix (Chiu, Leonard, and Tsui (1996)). If \( A \) is a \( p \times p \) real symmetric matrix, there exists a \( p \times p \) orthogonal matrix \( U \) and a diagonal matrix \( \Lambda \) such that \( A = U\Lambda U' \) and

\[
\exp(A) = U \left( \sum_{s=0}^{\infty} \frac{1}{s!} \Lambda^s \right) U' = U \exp(\Lambda) U'.
\]

Now let \( y_t = (y_{1t}, \ldots, y_{pt})' \) denote the \( p \)-dimensional asset return vector at time \( t \), and let \( H_t \) denote the matrix logarithm of the variance-covariance matrix of \( y_t \). The MESV model with leverage effects is given by

\[
y_t = \exp(H_t/2) \varepsilon_t, \quad \varepsilon_t \sim \text{i.i.d. } N(0, I_p), \quad t = 1, \ldots, n, \tag{4}
\]

\[
H_{t+1} = M + \tilde{\Phi} \odot (H_t - M) + E_t, \tag{5}
\]

\[
\begin{pmatrix} \varepsilon_t \\ \eta_t \end{pmatrix} \sim \text{i.i.d. } N_{p+q}(0, \Sigma), \quad \Sigma = \begin{pmatrix} I_p & \Sigma_{\varepsilon\eta} \\ \Sigma_{\eta\varepsilon} & \Sigma_{\eta\eta} \end{pmatrix}, \quad t = 1, \ldots, n-1, \tag{6}
\]

\[
h_1 \sim N_q(\mu, \Sigma_0), \tag{7}
\]

where \( \eta_t = \text{vech}(E_t), \ q = p(p + 1)/2, \ M = \{\mu_{ij}\}, \) and \( \tilde{\Phi} = \{\tilde{\phi}_{ij}\} \) are \( p \times p \) symmetric matrices of parameters, and \( \odot \) denotes the Hadamard product. For the identifiability, we
set the covariance matrix of $\varepsilon_t$ equal to $I_p$.

If we let $h_t = \text{vech}(H_t) = (h_{11,t}, h_{21,t}, \ldots, h_{p1,t}, h_{22,t}, \ldots, h_{pp,t})'$ denote the stacked column vector of the lower triangle elements of the $H_t$, then the “vech form” of (5) is given by

$$h_{t+1} = \mu + \Phi(h_t - \mu) + \eta_t,$$

(8)

with $\mu = \text{vech}(M) = (\mu_{11}, \mu_{21}, \ldots, \mu_{p1}, \mu_{22}, \ldots, \mu_{pp})'$, $\Phi = \text{diag}(\phi)$ (a diagonal matrix whose diagonal elements are equal to $\phi$) and $\phi = \text{vech}(\tilde{\Phi}) = (\phi_{11}, \phi_{21}, \ldots, \phi_{p1}, \phi_{22}, \ldots, \phi_{pp})'$. The number of parameters in the MESV model is $q(q + 2p + 3)/2$. The covariance matrix of the initial latent variable, $\Sigma_0$, is assumed to satisfy a stationary condition such that

$$\text{vec}(\Sigma_0) = (I_p - \Phi \otimes \Phi)^{-1} \text{vec}(\Sigma_{\eta\eta}).$$

We let $\Sigma_{\eta\eta} = \{\rho_{ij,\eta\eta}\sigma_{i,\eta\eta}\sigma_{j,\eta\eta}\}$, and $\Sigma_{\varepsilon\eta} = \{\rho_{ij,\varepsilon\eta}\sigma_{j,\eta\eta}\}$ where $\sigma_{i,\eta\eta}$ is the standard deviation of $\eta_{it}$ and $\rho_{ij,xy}$ is the correlation coefficient between $x_{it}$ and $y_{jt}$. Further, for convenience, we use the notation $E(i, j) = k$ based on the relationship $\eta_t = \text{vech}(E_t)$ such that the $(i, j)$-th element of $E_t$, $E_t(i, j)$, is equal to the $k$-th element of $\eta_t$, $\eta_{kt}$ (i.e., $E(1,1) = 1$, $E(2,1) = 2$, \ldots, $E(p,1) = p$, $E(2,2) = p + 1$, \ldots, $E(p,p) = p(p + 1)/2$). Thus, $\text{Cov}(\varepsilon_{it}, \eta_{kt}) = \rho_{ik,\varepsilon\eta}\sigma_{k,\eta\eta}$ is equal to $\text{Cov}(\varepsilon_{it}, E_t(i,j)) = \rho_{iE(i,j),\varepsilon\eta}\sigma_{E(i,j),\eta\eta}$.

Remark. Due to the nonlinearity of the matrix exponential transformation, the interpretation of the (untransformed) parameters will depend on the dimension of $y_t$. Thus, we consider estimates of transformed parameters to investigate the properties of interest, such as volatilities, correlations, principal components, and the news impact curve.

3 Bayesian estimation and associated particle filter

In this section, we describe an efficient Bayesian estimation method and an associated particle filter to compute the likelihood for the MESV model. Let $\theta = (\phi, \mu, \Sigma)$ and $h = (h'_1, \ldots, h'_n)'$ and $Y_n = (y_1, \ldots, y_n)$. Then the joint probability density function of $Y_n$
and \( h \) given \( \theta \) for (4) and (8) is given by

\[
f(Y_n, h|\theta) = f(h_1|\theta) \prod_{t=1}^{n-1} f(y_t, h_{t+1}|h_t, \theta)f(y_n|h_n, \theta)
\]

\[
\propto |\Sigma_0|^{-\frac{1}{2}} |\Sigma|^{-\frac{n-1}{2}} |\Sigma_{ee}|^{-\frac{1}{2}} \exp \left\{ \sum_{t=1}^{n} l_t - \frac{1}{2}(h_1 - \mu)'\Sigma_0^{-1}(h_1 - \mu) \right\}
\]

\[
\times \exp \left\{ -\frac{1}{2} \sum_{t=1}^{n-1} \{h_{t+1} - \mu - \Phi(h_t - \mu)\}'\Sigma_{\eta\eta}^{-1}\{h_{t+1} - \mu - \Phi(h_t - \mu)\} \right\},
\]

where \( l_t = -\frac{1}{2} \{\text{tr}(H_t) + (y_t - \mu_t)'\Sigma_t^{-1}(y_t - \mu_t)\} \) and

\[
\mu_t = \exp(H_t/2)m_t, \quad (10)
\]

\[
\Sigma_t = \exp(H_t/2)S_t \exp(H_t/2), \quad (11)
\]

\[
m_t = \Sigma_{\eta\eta}^{-1}(h_{t+1} - \mu - \Phi(h_t - \mu))I(t < n), \quad (12)
\]

\[
S_t = I_p - \Sigma_{\eta\eta}^{-1}\Sigma_{ee}I(t < n). \quad (13)
\]

### 3.1 Prior distributions

For prior distributions of \((\phi, \mu)\), we assume

\[
\frac{\phi_{ij} + 1}{2} \sim B(a_{ij}, b_{ij}), \quad i = 1, \ldots, p, \quad j = 1, \ldots, i, \quad (14)
\]

\[
\mu \sim \mathcal{N}_q(m_0^*, V_0^*), \quad (15)
\]

where \( B(a, b) \) denotes a beta distribution with parameters \( a \) and \( b \). To define a prior distribution of \( \Sigma \), we first denote

\[
\Sigma^{-1} = \begin{bmatrix}
\Sigma_{11} & \Sigma_{12} \\
\Sigma_{21} & \Sigma_{22}
\end{bmatrix}
\]

where \( \Sigma_{11}, \Sigma_{12} \) and \( \Sigma_{22} \) are \( p \times p, p \times q \) and \( q \times q \) matrices. Noting that \( \Sigma_{11} = I_p + \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21} \), we assume the prior distributions such that

\[
\text{vec}(\Sigma_{21})|\Sigma_{22} \sim \mathcal{N}_{pq}(\text{vec}(\Sigma_{22}\Delta_0), \Omega_0 \otimes \Sigma_{22}^{22}), \quad \Sigma_{22} \sim \mathcal{W}(n_0, R_0), \quad (16)
\]

where \( \mathcal{W}(n, R) \) denotes Wishart distribution with parameters \( n \) and \( R \).
3.2 MCMC algorithm

Using Equations (9), (14), (15) and (16), we obtain the joint posterior density function of $(\theta, h)$ given by

$$
\pi(\theta, h|Y_n) \propto f(Y_n|h, \theta) \times \prod_{i=1}^{p} \prod_{j=1}^{i} (1 + \phi_{ij})^{-1} \times f_N(\mu|m_0^0, V_0^0) \\
\times f_N(\text{vec}(\Sigma_{21}^{21})|\text{vec}(\Sigma_{22} \Delta_0), \Omega_0 \otimes \Sigma_{22}) \times |\Sigma_{22}|^{\frac{n-q-1}{2}} \exp \left\{ -\frac{1}{2} \text{tr} \left( R_0^{-1} \Sigma_{22} \right) \right\},
$$

where $f_N(\cdot|\mu, \Sigma)$ denotes a normal density with mean $\mu$ and covariance matrix $\Sigma$. To obtain the posterior quantities of the parameters $\theta$ and volatility variables $\{h_t\}_{t=1}^n$ from the posterior distribution, we implement the MCMC algorithm in six blocks:

1. Initialize $h, \phi, \mu, \Sigma$.

2. Generate $h|\phi, \mu, \Sigma, Y_n$.

3. Generate $\mu|\phi, \Sigma, h, Y_n$.

4. Generate $\Sigma|\phi, \mu, h, Y_n$.

5. Generate $\phi|\mu, \Sigma, h, Y_n$.

6. Go to Step 2.

3.2.1 Generation of $h$

As is often pointed out in the literature, it is important to sample the latent volatility variables $\{h_t\}_{t=1}^n$ in an efficient way. The simple sample method, which samples one $h_t$ at a time given the other $h_s$’s and parameters, is known to be inefficient, often producing highly autocorrelated MCMC samples. This is because the the estimates of autoregressive parameters $\phi_i$ are often found to be very close to one in empirical studies. Thus, we propose the sampling method based on a multi-move sampler which samples a set of $h_t$’s as one block at a time (see e.g.Shephard and Pitt (1997), Watanabe and Omori (2004), Omori and Watanabe (2008), Ishihara and Omori (2012)). We first describe a simple algorithm which we call a single-move sampler as we use it as a benchmark to evaluate the estimation efficiencies of the multi-move algorithm.
**Single-move sampler.** Let \( \Sigma_h = \Sigma_{\eta \eta} - \Sigma_{\eta \varepsilon} \Sigma_{\varepsilon \eta} \) and \( \mu_{h,t+1} = \mu + \Phi(h_t - \mu) + \Sigma_{\eta \varepsilon} \exp(-H_t/2) y_t. \) Then, the conditional posterior density of \( h_t \) given \( \{h_s\}_{s \neq t}, \Phi \) and \( \Sigma \) is

\[
\pi(h_t | \{h_s\}_{s \neq t}, \Phi, \Sigma, Y_n) \propto \exp \left\{ -\frac{1}{2}(h_t - \gamma_t)' \Gamma_t^{-1}(h_t - \gamma_t) + g(h_t) \right\},
\]

where

\[
g(h_t) = -\frac{1}{2} \text{tr}(H_t) - \frac{1}{2} y_t' \exp(-H_t/2) S_t^{-1} \exp(-H_t/2) y_t + (h_{t+1} - \mu - \Phi(h_t - \mu))' \Sigma_h^{-1} \Sigma_{\eta \varepsilon} \exp(-H_t/2) y_t I(t < n),
\]

and

\[
\Gamma_t = \begin{cases} 
(\Phi \Sigma_h^{-1} \Phi + \Sigma_0^{-1})^{-1}, & t = 1, \\
(\Sigma_h^{-1} + \Phi \Sigma_h^{-1} \Phi)^{-1}, & 1 < t < n, \\
\Sigma_h, & t = n,
\end{cases}
\]

\[
\gamma_t = \begin{cases} 
\Gamma_t \Phi \Sigma_h^{-1}(h_2 - (I_p - \Phi) \mu), & t = 1, \\
\Gamma_t (\Phi \Sigma_h^{-1}(h_{t+1} - (I_p - \Phi) \mu) + \Sigma_h^{-1} \mu_{h,t}), & 1 < t < n, \\
\mu_{h,t}, & t = n.
\end{cases}
\]

We generate a candidate \( h_t^\dagger \) from \( h_t^\dagger \sim \mathcal{N}_q(\gamma_t, \Gamma_t) \) and accept it with probability

\[
\min \left\{ \exp\{g(h_t^\dagger) - g(h_t)\}, 1 \right\}, \quad t = 1, \ldots, n.
\]

**Multi-move sampler.** In this algorithm, we first divide \( h \) into several blocks, and sample one block at a time from its conditional posterior distribution given other blocks. Using the Taylor expansion of the logarithm of the conditional posterior density around the conditional posterior mode, we derive a candidate distribution as a posterior distribution for some linear Gaussian state space model to exploit various smoothing and simulation algorithms as in Omori and Watanabe (2008).

To generate \( \{h_t\}_{t=s+1}^{s+m} \) given other \( h_t \)'s, for example, we sample the normalized disturbances \( \{x_t\}_{t=s+1}^{s+m-1} \) instead of \( \{h_t\}_{t=s+1}^{s+m} \) since such a sampling method is known to reduce the MCMC sample autocorrelations where

\[
x_t = \Sigma_{\eta \eta}^{-1/2} \eta_t, \quad t = 1, \ldots, n - 1, \quad x_0 = \Sigma_0^{-1/2} \eta_0,
\]

8
and $\Sigma_{\eta\eta}^{1/2}$, $\Sigma_0^{1/2}$ denote Choleski decompositions such that $\Sigma_{\eta\eta} = \Sigma_{\eta\eta}^{1/2} \Sigma_{\eta\eta}^{1/2}'$ and $\Sigma_0 = \Sigma_0^{1/2} \Sigma_0^{1/2}'$.

Consider the following linear Gaussian state space model:

\[
\begin{align*}
\hat{y}_t &= Z_t \alpha_t + G_t u_t, \quad t = s + 1, \ldots, s + m, \quad (18) \\
\alpha_{t+1} &= \Phi \alpha_t + K_t u_t, \quad t = s + 1, \ldots, s + m - 1, \quad (19) \\
u_t &= (\xi_t', \xi_t')' \sim N_{2p} (0, I), \\
\end{align*}
\]

where $K_t = [O, \Sigma_{\eta\eta}^{1/2}]$ for $t = 1, \ldots, n - 1$ and $K_0 = [O, \Sigma_0^{1/2}]$, and $\hat{y}_t$, $Z_t$, $G_t$ are computed as follows:

1. First we set $\hat{x}_t = x_t$ ($t = s, \ldots, s + m - 1$) where $x_t$ is a current sample.

2. Define $d_t$, $A_t$ and $B_t$ as in Appendix A. Let $\hat{d}_t$, $\hat{A}_t$ and $\hat{B}_t$ denote the vector and matrices evaluated at $x_t = \hat{x}_t$ ($t = s, \ldots, s + m - 1$). Further, let $\hat{\alpha}_{t+1} = \Phi \hat{\alpha}_t + \Sigma_{\eta\eta}^{1/2} \hat{x}_t$ ($t = s, \ldots, s + m - 1$) with $\hat{\alpha}_s = h_s - \mu$.

3. Set $b_s = 0$ and $\hat{B}_{s+m+1} = O$. Compute

\[
\begin{align*}
D_t &= \hat{A}_t - \hat{B}_t D_{t-1}^{-1} \hat{B}_t', \quad b_t = \hat{d}_t - \hat{B}_t D_{t-1}^{-1} b_{t-1}, \quad t = s + 1, \ldots, s + m. \\
\end{align*}
\]

4. Let

\[
\begin{align*}
\hat{y}_t &= \hat{\alpha}_t + D_t^{-1} (b_t + \hat{B}_t' \hat{\alpha}_t+1), \quad Z_t = I_p + D_t^{-1} \hat{B}_t' \Phi, \\
G_t &= [D_t^{-1/2}, D_t^{-1} \hat{B}_t' \Sigma_{\eta\eta}], \quad t = s + 2, \ldots, s + m, \\
\end{align*}
\]

where $D_t^{1/2}$ denotes a Choleski decomposition such that $D_t = D_t^{1/2} D_t^{1/2}'$.

5. Implement the disturbance smoother (Koopman (1993)) to obtain $\{\hat{x}_t\}_{t=s}^{s+m-1}$, the mode of the conditional posterior density of $\{x_t\}_{t=s}^{s+m-1}$ for the model (18) and (19).

If the the mode converges (however, usually several iterations will be sufficient to construct a proposal distribution), save $\hat{y}_t$, $Z_t$ and $G_t$. Otherwise, go to Step 2.

Then we apply the simulation smoother (e.g. de Jong and Shephard (1995), Durbin and Koopman (2002)) to generate a candidate $\{x_t^1\}_{t=s}^{s+m-1}$ from this state space model for
Metropolis-Hastings algorithm. We accept a candidate with probability
\[
\min \left\{ 1, \frac{f(\{x_t\}_{t=s}^{s+m-1}) f^*(\{x_t\}_{t=s}^{s+m-1})}{f(\{x_t\}_{t=s}^{s+m-1}) f^*(\{x_t\}_{t=s}^{s+m-1})} \right\},
\]
where \( f(\{x_t\}_{t=s}^{s+m-1}) \) and \( f^*(\{x_t\}_{t=s}^{s+m-1}) \) denote conditional posterior densities of \( \{x_t\}_{t=s}^{s+m-1} \) for MESV model and the linear Gaussian state space model (18)–(19).

### 3.2.2 Generation of \( \Sigma \)

Since the \( p \times p \) leading principal submatrix of \( \Sigma \) is an identity matrix, we first generate \( \Sigma^{22} \) and then sample \( \text{vec}(\Sigma^{21}) \) conditional on \( \Sigma^{22} \), to conduct MH algorithm using the property of Wishart distribution (see, e.g., Theorem 3.3.9 of Gupta and Nagar (2000)).

Let
\[
R^{-1} = \begin{bmatrix} R^{11} & R^{12} \\ R^{21} & R^{22} \end{bmatrix} = \begin{bmatrix} \sum_{t=1}^{n-1} \varepsilon_t \varepsilon'_t & \sum_{t=1}^{n-1} \varepsilon_t \eta'_t \\ \sum_{t=1}^{n-1} \eta_t \varepsilon'_t & \sum_{t=1}^{n-1} \eta_t \eta'_t \end{bmatrix},
\]
where \( R^{11}, R^{12} = R^{21}, R^{22} \) are \( p \times p, p \times q, q \times q \) matrices, \( \varepsilon_t = \exp(-H_t/2)\eta_t \) and \( \eta_t = h_{t+1} - \mu - \Phi(h_t - \mu) \). Using \( \text{tr}(AB) = \text{vec}(A')'\text{vec}(B) \) and \( \text{vec}(AXB) = (B' \otimes A)\text{vec}(X) \), for \( X(n \times n), A(m \times n) \) and \( B(n \times m) \), the joint conditional posterior probability density of \( \Sigma^{12} \) and \( \Sigma^{22} \) is obtained as follows.

\[
\pi(\Sigma^{12}, \Sigma^{22}|\Phi, h, Y_n) = \pi(\Sigma^{22}|\Phi, h, Y_n) \pi(\text{vec}(\Sigma^{21})|\Sigma^{22}, \Phi, h, Y_n) \\
\propto h(\Sigma) \times |\Sigma|^{-\frac{n-1}{2}} \exp \left\{ -\frac{1}{2} \text{tr} (R^{-1} \Sigma) \right\} \times |\Sigma^{22}|^{-\frac{n_q-1}{2}} \exp \left\{ -\frac{1}{2} \text{tr} (R_0^{-1} \Sigma^{22}) \right\} \\
\times f_N(\text{vec}(\Sigma^{21})|\text{vec}(\Sigma^{22} \Delta_0), \Omega_0 \otimes \Sigma^{22}) \\
\propto h(\Sigma) \times |\Sigma^{22}|^{-\frac{n_q-1}{2}} \exp \left\{ -\frac{1}{2} \text{tr} \left\{ (R^{22} - R^{21} R^{11-1} R^{12} + R_0^{-1}) \Sigma^{22} \right\} \right\} \\
\times \exp \left\{ -\frac{1}{2} \text{vec}(\Sigma^{21} + \Sigma^{22} R^{21} R^{11-1})' (R^{11} \otimes \Sigma^{22-1}) \text{vec}(\Sigma^{21} + \Sigma^{22} R^{21} R^{11-1}) \right\} \\
\times f_N(\text{vec}(\Sigma^{21})|\text{vec}(\Sigma^{22} \Delta_0), \Omega_0 \otimes \Sigma^{22}) \\
\propto h(\Sigma) \times |\Sigma^{22}|^{-\frac{n_q-1}{2}} \exp \left\{ -\frac{1}{2} \text{tr} (R^{-1}_1 \Sigma^{22}) \right\} \times f_N(\text{vec}(\Sigma^{21})|\text{vec}(\Sigma^{22} \Delta_1), \Omega_1 \otimes \Sigma^{22})
\]

10
where \( n_1 = n_0 + n - 1 \), \( R_{11}^{-1} = R_{22} - \Delta_1 \Omega_1^{-1} \Delta_1' + R_0^{-1} + \Delta_0 \Omega_0^{-1} \Delta_0' \) and

\[
\begin{align*}
\Omega_1 &= (R_{11} + \Omega_0^{-1})^{-1}, \\
\Delta_1 &= (-R_{21} + \Delta_0 \Omega_0^{-1}) \Omega_1 \\
h(\Sigma) &= |\Sigma_0|^{-\frac{1}{2}} \exp \left\{ -\frac{1}{2} (h_1 - \mu)' \Sigma_0^{-1} (h_1 - \mu) \right\}.
\end{align*}
\]

Thus, we generate a candidate \( \Sigma^\dagger \) in three steps.

1. Draw \( \Sigma^{22\dagger} \sim \mathcal{W}(n_1, R_1) \).
2. Draw \( \text{vec}(\Sigma^{21\dagger})|\Sigma^{22\dagger} \sim \mathcal{N}_{pq}(\text{vec}(\Sigma^{22\dagger} \Delta_1), \Omega_1 \otimes \Sigma^{22\dagger}) \).
3. Compute \( \Sigma_{\eta\eta}^\dagger = -\Sigma^{12\dagger} \Sigma^{22\dagger}^{-1} \) and \( \Sigma_{\eta\epsilon}^\dagger = \Sigma^{22\dagger}^{-1} + \Sigma_{\eta\epsilon} \Sigma_{\epsilon\epsilon}^\dagger \).

and accept it with probability

\[
\min \left\{ \frac{h(\Sigma^\dagger)}{h(\Sigma)}, 1 \right\}.
\]

### 3.2.3 Generation of \((\mu, \phi)\)

**Generation of \( \mu \).** The conditional posterior distribution of \( \mu \) is

\[
\mu|\Sigma, \Phi, h, Y_n \sim \mathcal{N}_q(m_1^*, V_1^*),
\]

where

\[
\begin{align*}
V_1^* &= \left( \Sigma_0^{-1} + \sum_{t=1}^{n-1} (I_p - \Phi)' \Sigma_h^{-1} (I_p - \Phi) + V_0^{-1} \right)^{-1}, \\
m_1^* &= V_1^* \left[ \sum_{t=1}^{n-1} (I_p - \Phi)' \Sigma_h^{-1} \{ h_{t+1} - \Phi h_t - \Sigma_{\epsilon\eta} \exp(-H_t / 2) y_t \} + \Sigma_0^{-1} h_1 + V_0^{-1} m_0^* \right].
\end{align*}
\]

**Generation of \( \phi \).** Let \( A = \sum_{t=1}^{n-1} (h_t - \mu)(h_t - \mu)' \), \( B = \sum_{t=1}^{n-1} ((h_t - \mu)y_t' \exp(-H_t / 2) \Sigma^{12} + (h_t - \mu)(h_{t+1} - \mu)' \Sigma^{22}) \) and \( b \) denote a vector whose \( i \)-th element is equal to the \((i, i)\)-th element of \( B \). Then the conditional posterior probability density function of \( \phi \) is

\[
\begin{align*}
\pi(\phi|\Sigma, \alpha, Y_n) &\propto \exp \left\{ -\frac{1}{2} \text{tr}(\Phi \Sigma_{22} \Phi A) - 2 \text{tr}(\Phi B) \right\} \times k(\phi) \\
&\propto f_N(\phi|\mu_\phi, \Sigma_\phi) \times k(\phi), \\
k(\phi) &= |\Sigma_0|^{-\frac{1}{2}} \pi(\phi) \exp \left\{ -\frac{1}{2} \alpha_1' \Sigma_0^{-1} \alpha_1 \right\}.
\end{align*}
\]
where $\mu_\phi = \Sigma_\phi b$, $\Sigma_\phi^{-1} = \Sigma^{22} \odot A$ and $\odot$ denotes the Hadamard product. To sample $\phi$ from its conditional posterior distribution using MH algorithm, we generate a candidate from a truncated normal distribution over the region $R$, $\phi^* \sim T\mathcal{N}_R(\mu_\phi, \Sigma_\phi)$, $R = \{\phi : |\phi_j| < 1, j = 1, \ldots, p\}$ and accept it with probability $\min\{k(\phi^*)/k(\phi), 1\}$.

### 3.3 Associated particle filter

We describe the associated auxiliary particle filter introduced by Pitt and Shephard (1999) for the MESV model to compute the log likelihood function. In Section 5, we use this algorithm to calculate DIC (deviance information criterion proposed by Spiegelhalter, Best, Carlin, and van der Linde (2002)). Let

$$f(y_t|h_t) = (2\pi)^{-\frac{p}{2}} |\mathbf{H}_t|^{-\frac{1}{2}} \exp \left\{-\frac{1}{2} \mathbf{y}_t \mathbf{H}_t^{-1} \mathbf{y}_t \right\},$$

$$f(h_{t+1}|y_t, h_t, \theta) = (2\pi)^{-\frac{p}{2}} |\Sigma_h|^{-\frac{1}{2}} \exp \left\{-\frac{1}{2} (h_{t+1} - \mu_{h,t+1})' \Sigma_h^{-1} (h_{t+1} - \mu_{h,t+1}) \right\},$$

and $f(h_t|Y_t, \theta)$ denote a conditional density of $h_t$ given $(Y_t, \theta)$. Then the conditional joint density function of $h_{t+1}, h_t$, given $(Y_{t+1}, \theta)$ is

$$f(h_{t+1}, h_t|Y_{t+1}, \theta) \propto f(y_{t+1}|h_{t+1}) f(h_{t+1}|y_t, h_t, \theta) f(h_t|Y_t, \theta).$$

We first construct an importance function to sample from the conditional joint distribution. Let $f(h_t|Y_t, \theta)$ denote a discrete probability mass function approximating $f(h_t|Y_t, \theta)$ and

$$g(h_{t+1}, h_t^i|Y_{t+1}, \theta) \propto f(y_{t+1}|h_{t+1}^i) f(h_{t+1}|y_t, h_t^i, \theta) f(h_t|Y_t, \theta)$$

$$\propto f(h_{t+1}|y_t, h_t^i, \theta) g(h_t^i|Y_{t+1}, \theta),$$

where

$$g(h_t^i|Y_{t+1}, \theta) = \frac{f(y_{t+1}|h_t^i, \theta) f(h_t^i|Y_{t+1}, \theta)}{\sum_{j=1}^J f(y_{t+1}|h_t^j, \theta) f(h_t^j|Y_{t+1}, \theta)},$$

$$f(y_{t+1}|\mu_{h,t+1}^i) = (2\pi)^{-\frac{p}{2}} |\mathbf{M}_t^i|^{-\frac{1}{2}} \exp \left\{-\frac{1}{2} \mathbf{y}_{t+1}' \exp(-\mathbf{M}_t^i y_{t+1}) \right\},$$

$$\mu_{h,t+1}^i = \text{vech}(\mathbf{M}_t^i) = \mu + \Phi(h_t^i - \mu) + \Sigma_y \exp(-\mathbf{H}_t^i/2) \mathbf{y}_t.$$
(a) Generate \( h_1^i \sim \mathcal{N}(\mu, \Sigma_0) \) (\( i = 1, \ldots, I \)).
(b) Compute \( w_i = f(y_1|h_1^i, \theta) \) and save \( \bar{w}_1 = \frac{1}{I} \sum_{i=1}^I w_i \).
(c) Let \( \hat{f}(h_1^i|Y_1, \theta) = \pi_1^i = w_i / \sum_{j=1}^I w_j \) (\( i = 1, \ldots, I \)).

2. Generate \( (h_{t+1}^i, h_t^i) \sim g(h_{t+1}^i, h_t^i|Y_{t+1}, \theta) \) (\( i = 1, \ldots, I \)):
   (a) Compute \( \mu_{h,t+1}^i = \mu + \Phi(h_t^i - \mu) + \Sigma_{ye} \exp(-H_t^i/2) y_t \).
   (b) Generate \( h_{t+1}^i \sim g(h_t^i|Y_{t+1}, \theta) \).
   (c) Generate \( h_{t+1}^i \sim f(h_{t+1}^i|y_t, h_t^i, \theta) \).

Then compute
\[
    w_i = \frac{f(y_{t+1}|h_{t+1}^i) f(h_{t+1}^i|y_t, h_t^i, \theta) \hat{f}(h_t^i|Y_t, \theta)}{g(h_{t+1}^i, h_t^i|Y_{t+1}, \theta)}, \quad i = 1, \ldots, I,
\]
and save
\[
    \bar{w}_t = \frac{1}{I} \sum_{i=1}^I w_i.
\]
Further let \( \hat{f}(h_{t+1}^i|Y_{t+1}, \theta) = \pi_{t+1}^i = w_i / \sum_{j=1}^I w_j \) (\( i = 1, \ldots, I \)).

3. Set \( t \leftarrow t + 1 \). Go to Step 2.

Then, as \( I \to \infty \), we obtain \( \sum_{t=1}^n \log \bar{w}_t \overset{p}{\to} \sum_{t=1}^n \log f(y_t|Y_{t-1}, \theta) \).
4 Illustrative example with simulated data

This section shows the efficiency of our proposed method using a simulated data. To replicate the dynamics of the stock return series, we use the MESV model with

\[ \mu_{ij} = \begin{cases} 0.5, & i = j, \\ 0.2, & i \neq j, \end{cases} \quad \phi_{ij} = \begin{cases} 0.97, & i = j, \\ 0.85, & i \neq j, \end{cases} \]

\[ \rho_{E(j,k),\varepsilon_n} = \text{Corr}(\varepsilon_t, E_t(j,k)) = \begin{cases} -0.3, & i = j = k, \\ -0.1, & \text{otherwise,} \end{cases} \]

\[ \rho_{E(i,j)E(k,l),\eta_n} = \text{Corr}(E_t(i,j), E_t(k,l)) = \begin{cases} 0.3, & i = j \neq k = l, \\ 0.1, & \text{otherwise,} \end{cases} \]

\[ \sigma_{E(i,j),\eta_n} = \sqrt{\text{Var}(E_t(i,j))} = \begin{cases} 0.2, & i = j \\ 0.15, & \text{otherwise,} \end{cases} \]

which are based on typical values in our empirical studies where \( E(1,1) = 1, E(2,1) = 2, E(3,1) = 3, E(2,2) = 4, E(3,2) = 5 \) and \( E(3,3) = 6 \).

We generate \( n = 4,000 \) observations with \( p = 3 \) and \( q = 6 \). Prior distributions are assumed to be as follows.

\[ \mu \sim N_q(0, 5I_q), \]

\[ \frac{\phi_{ij} + 1}{2} \sim \begin{cases} \mathcal{B}(20, 3/2), & i = j, \\ \mathcal{B}(1, 1), & i \neq j, \end{cases} \]

\[ \Sigma^{22} \sim \mathcal{W}(6, (6\Sigma^{22*})^{-1}), \]

\[ \text{vec}(\Sigma^{21})|\Sigma^{22} \sim N_{pq}(0, (5I_p \otimes \Sigma^{22})), \]

where \( \Sigma^{22*} \) is a true covariance matrix satisfying \( E(\Sigma^{22}) = \Sigma^{22*} \). The mean and the standard deviation of the prior distribution of \( \phi_{ii}, j = 1, 2, 3 \) are set 0.86 and 0.11 respectively.

Using the multi-move (single-move) sampler, we draw 110,000 (550,000) posterior samples and discard the first 10,000 (50,000) samples as burn-in periods.

**Parameter estimation.** Tables 1, 2, and 3 show the estimation summaries for all parameters via the multi-move sampler. The posterior means and 95% credible intervals suggest that the estimates are sufficiently close to true values, which indicates that our proposed estimation algorithm works well. The inefficiency factors are also shown for the multi-move sampler.
The inefficiency factor is the ratio of the numerical variance of the estimate from the MCMC samples relative to that from hypothetical uncorrelated samples, and is defined as $1 + 2 \sum_{s=1}^{\infty} \rho_s$ where $\rho_s$ is the sample autocorrelation at lag $s$. It suggests the relative number of correlated draws necessary to attain the same variance of the posterior sample mean from the uncorrelated draws (see e.g. Chib (2001)).

Table 1: Posterior means, 95% credible intervals, and inefficiency factors.

<td>438 [761]</td>
<td></td>
</tr>
</tbody>
</table>

$$\sigma_{E(i,j),\eta\eta} = \sqrt{\text{Var}(E_t(i,j))}$$

The inefficiency factors for the single-move sampler are about three times larger than those for the multi-move sampler. This implies that our proposed multi-move sampler is more efficient than the single-move sampler as we expected.
Table 2: Posterior means, 95% credible intervals and inefficiency factors.

\[ \rho_{E(j,k),E(j,k)} = \text{Corr}(\varepsilon_{it}, E_t(j,k)) \]

5 Application to trivariate asset returns data

5.1 Data

This section applies our proposed MESV model to returns of three assets: (1) Tokyo stock price index (TOPIX), (2) the Japan government bond clean price index (JGB) provided by Thomson Reuters Datastream), and (3) the currency exchange rate of Japanese Yen to U.S. Dollar (Yen/USD) announced by the Federal Reserve Bank at noon in New York. We excluded those days when at least one of three observations is not reported. The sample period is from January 4, 1995 to July 30, 2010 for a total of 3710 observations. Figure 1 shows the time series plot of three returns which are 100 times the differences of the logarithm of the asset values.

5.2 Estimation results

5.2.1 Univariate SV and MSV models

We first estimate the (univariate) SV model with leverage effect defined by (1)–(3) with \( p = 1 \) for each series, and the constant correlation multivariate SV (MSV) model defined by (1)–(3) with \( p = 3 \). For the SV model, the prior distributions for \( \phi_i \) and \( \Sigma_i \) are assumed
to be
\[
\phi_i + \frac{1}{2} \sim \mathcal{B}(20, 1.5), \quad \Sigma_i \sim \mathcal{IW}(5, (5\Sigma^*)^{-1}), \quad \Sigma^* = \begin{pmatrix} 1 & 0 \\ 0 & 0.04 \end{pmatrix}, \quad i = 1, 2, 3.
\]

For the MSV model, we assume prior distributions such that
\[
\phi_i + \frac{1}{2} \sim \mathcal{B}(20, 1.5), \quad i = 1, \ldots, 5, \quad \Sigma \sim \mathcal{IW}(6, (6\Sigma^*)^{-1}),
\]
where
\[
\Sigma^* = \begin{pmatrix} 1.5^2 & 0 & 0 \\ 0 & 0.5I_2 & 0 \\ 0.2^2(0.3I_3 + 0.713I_3^T) \end{pmatrix}.
\]

Tables 4 and 5 show summary statistics of posterior distributions of the parameters for the SV and the MSV models. In both models, the posterior means of the autoregressive parameters ($\phi_i$'s) are very high (between 0.938 and 0.972 in the SV model and between 0.948 and 0.966 in the MSV model) showing that volatilities are highly persistent.

</table>

1: TOPIX, 2: JGB, 3: Yen/USD.

Also, the leverage effects are estimated to be negative as in the previous literature where that of the stock return ($-0.511$ in the SV model and $-0.445$ in the MSV model) is much stronger than those of the bond return and the foreign exchange return ($-0.176$ and $-0.201$ in the SV model, $-0.177$ and $-0.167$ in the MSV model). In the MSV model, the cross
leverage effect, $\rho_{12,\eta\eta}$, (from the stock return to the bond return volatility) is estimated to be positive (0.189), while the opposite effect, $\rho_{21,\eta\eta}$, (from the bond return to the stock return volatility) is not credible in the sense that its 95% credible interval doesn’t include zero. This implies the increase in the stock return at time $t$ causes the high volatility in the bond return at time $t+1$, but the fall of the bond return seems to have a limited impact on the stock return volatility.

5.2.2 MESV model

Next, we estimate the MESV model assuming that prior distributions are

\[
\phi_{ij} + 1 \sim \begin{cases} 
B(20, 3/2), & \text{if } i = j, \\
B(33/4, 11/4), & \text{otherwise},
\end{cases}
\]

\[
\mu \sim \mathcal{N}_q(0, 5I_q),
\]

\[
\Sigma^{22} \sim \text{W}(6, (6\Sigma^{22*})^{-1}), \quad \text{vec}(\Sigma^{22})|\Sigma^{22} \sim \mathcal{N}_{pq}(0, (5I_p) \otimes \Sigma^{22}).
\]

The \((i, j)\)-th element of $\Sigma_{22}^{*-1}$ is $\rho_{E(k,l)E(m,n),\eta\eta}^* \sigma_{E(k,l),\eta\eta}^* \sigma_{E(m,n),\eta\eta}^*$ such that

\[
\rho_{E(k,l)E(m,n),\eta\eta}^* = \begin{cases} 
0.6, & \text{if } k = l \neq m = n, \\
0.2, & \text{otherwise},
\end{cases}
\]

\[
\sigma_{E(k,l),\eta\eta}^* = 0.2, \quad 1 \leq l \leq k \leq 3.
\]
The mean and the standard deviation of the prior distribution of $\phi_{ij}$, $i \neq j$ are set 0.5 and 0.5 respectively.

We draw 220,000 samples for the multi-move sampler discarding the first 20,000 samples as a burn-in-period. The number of blocks is set to 185 based on several trials.

1:TOPIX, 2:JGB, 3:Yen/USD

$$\sigma_{E(i,j),\eta} = \sqrt{\text{Var}(E_{t(i,j)})}$$

The estimation results are summarized in the Tables 6, 7 and 8. We notice that the parameters of the diagonal elements of $H_t$ (the 1st, 4th, and 6th elements of $H_t$) are similar to those of MSV models. The autoregressive parameters of log volatilities, $(\phi_{11}, \phi_{22}, \phi_{33})$, are (0.968, 0.968, 0.953) while $(\phi_1, \phi_2, \phi_3)$ for MSV models are (0.965, 0.966, 0.948). The posterior means of $(\mu_{11}, \mu_{22}, \mu_{33})$ are (0.286, -2.923, -0.929), while $(\log \sigma^2_{1,\epsilon\epsilon}, \log \sigma^2_{2,\epsilon\epsilon}, \log \sigma^2_{3,\epsilon\epsilon})$ evaluated at the posterior means in Table 5 are (0.385, -2.582, -0.825). Further, the estimates of standard deviations of the $\eta_{it}$, $(\sigma_{E(1,1),\eta\eta}, \sigma_{E(2,2),\eta\eta}, \sigma_{E(3,3),\eta\eta})$, are (0.176, 0.211, 0.204), while those of $(\sigma_{1,\eta\eta}, \sigma_{2,\eta\eta}, \sigma_{3,\eta\eta})$ are (0.191, 0.210, 0.225). Regarding the leverage effects, the estimates of $(\rho_{1E(1,1),\epsilon\eta}, \rho_{2E(2,2),\epsilon\eta}, \rho_{3E(3,3),\epsilon\eta})$ are (-0.467, -0.109, -0.166), while $(\rho_{11,\epsilon\eta}, \rho_{22,\epsilon\eta}, \rho_{33,\epsilon\eta})$ for the MSV models are (-0.445, -0.177, -0.167).

1:TOPIX, 2:JGB, 3:Yen/USD
Estimated volatilities and correlations. However, as mentioned in Section 2, the parameters such as $\Phi$, $M$ and $\Sigma_{\epsilon\eta}$ in the MESV model do not always correspond to those of the stock, the bond, and the exchange rate as they are in the MSV model. Thus, to interpret the estimation results of the MESV model in more intuitive way, we consider the posterior means of time-varying volatilities of each series, dynamic correlations among three returns and news impact curves using MCMC simulation technique.

First, we consider the posterior means of the square root of the time-varying variances as shown in Figure 2. The estimated volatility series of the TOPIX returns sharply increased in September 2008, corresponding to the financial crisis during which Lehman Brothers filed for Chapter 11 bankruptcy protection. The volatilities of the JGB index returns increased in December 1998 and in September 2003 when the index dropped (or equivalently, the JGB interest rate ran up) in both periods. In December 1998, the JGB is supplied excessively because the Japanese government issued a large amount of JGB for the economic-stimulus measure, and the Ministry of Finance Japan announced to stop buying the new bonds in this month. Moreover, the Moody’s downgraded the JGB rating in November 1998. In this month, the Nippon Credit Bank was brought under government control because of a large amount of the bad debt. In the mid 2003s, following the increase of the US bond interest rate and the economic boom, the deflationary concerns of Japan toned down. The expectation for the lifting of the zero-interest-rate policy of the Bank of Japan, the JGB interest rate shot up in June and September of 2003. The volatilities of the Yen/USD increase after the August 1998 when the ruble devaluation and the Long Term Capital Management report a large loss. Especially, the USD fell from 135.6 yen to 117 yen in five days of early October 1998. This is just after the decision of the monetary relaxation policy in the USA on September 29th and issuing the G-7 communique which urged the injection of taxpayers’ money to financial institutions in Japan on October 5th.

Next, we investigate the posterior means of dynamic correlations among three returns as shown in Figure 3. These correlations are computed using the MCMC samples of the covariance and the variances that are elements of $\exp(H_t)$ which is the matrix exponential transformation of the log volatility matrix $H_t$. The correlations between the stock and the JGB returns largely fluctuate taking negative values where they drop to less than $-0.86$ in January 2008 during the downturn of the stock market. The correlations between the stock market and the exchange rate returns fluctuates around zero. It is noted that this takes negative values during Asian crisis period from July 1997 to August 1998. In this period, the yen kept weakening and Japanese stock prices dropped. The JGB returns and
the exchange rate returns seem to have no correlation throughout the sample period.

Figure 2: Posterior means of the square root of time-varying variances. Top: TOPIX, middle: JGB, bottom: Yen/USD.

Figure 3: Posterior means of time-varying correlations. Top: (TOPIX, JGB), middle: (TOPIX, Yen/USD), bottom: (JGB, Yen/USD).
Dynamic principal components implied by the MESV model. Furthermore, we can interpret our estimation results for MESV model in terms of the principal component analysis. Using the diagonalization to calculate the matrix exponential, we calculate the principal components of $y_t$. Since $H_t = U_t \Lambda_t U_t'$ where $\Lambda_t = \text{diag}(\lambda_{1t}, \lambda_{2t}, \lambda_{3t})$ and $U_t U_t' = I_3$, we obtain

$$U_t' y_t = \text{diag}(\exp(\lambda_{1t}/2), \exp(\lambda_{2t}/2), \exp(\lambda_{3t}/2)) \varepsilon_t^*,$$  \hspace{1cm} (20)

where $\varepsilon_t^* := U_t' \varepsilon_t \sim \mathcal{N}(0, I_3)$, and we assume $\lambda_{1t} \geq \lambda_{2t} \geq \lambda_{3t}$. The $i$-th element of $U_t' y_t$ in (20) can be interpreted as the $i$-th principal component of the returns at time $t$. Moreover, the row vector of the loading matrix $U_t'$ can be interpreted as a weight vector for the portfolio which represents the stock market principal component. Top and middle panels of Figure 4 show time series plots of the principal components, $U_t' y_t$, $t = 1, \ldots, n$ and their standard deviations.

Figure 4: Posterior means of principal components series (top) and their standard deviations (middle), and contribution ratio series (bottom).
The first principal component (blue lines) fluctuates sharply and its variance shot up when at least one of the volatilities of the original series increase around 1998, 2003 and 2008. The bottom panel of Figure 4 shows the contribution ratio of each principal component, defined by
\[ \frac{\exp(\lambda_{1t})}{\sum_{i=1}^{3} \exp(\lambda_{it})}, \frac{\exp(\lambda_{2t})}{\sum_{i=1}^{3} \exp(\lambda_{it})}, \frac{\exp(\lambda_{3t})}{\sum_{i=1}^{3} \exp(\lambda_{it})} \] for \( t = 1, \ldots, n \). The ratio of the first principal component (blue part) increases when one of three return series became more volatile. On the other hand, the contribution ratio of the second series (green part) decreases in those volatile periods. The third principal component (red part) has the ratio less than 10% over almost all the sample period. This implies that most of the variation of the original three series can be explained by two principal components.

**News impact curves.** Finally, to show how the shocks in the returns at time \( t \) affect the volatilities at time \( t + 1 \), we describe the news impact curve following Engle and Ng (1993). Similar ideas for stochastic volatility models are discussed by Yu (2005) and Asai and McAleer (2009). Let \( H_t = M \) and \( E_t = O \) and consider the case where \( h_{t+1} = \mu + \Sigma_{\gamma e} \exp(-M/2)Y_t \).

![Figure 5: Posterior mean (solid line) and 95% interval (dotted lines) of the news impact curve for the one-step-ahead conditional covariances of \( y_{t+1} \) when \( H_t = M \) and \( E_t = O \).](image)

(* The domain of the estimated curve is restricted to the range within ±4 sample standard deviation of actual returns for each \( y_{it} \).)
Figure 5 shows the posterior news impact curves on standard deviations and correlations of $y_{t+1}$ from $y_t$, obtained by calculating the posterior means and the 95% intervals of the normalized $\exp(H_{t+1})$ under the various shocks of $y_t$. The horizontal and vertical axes show the values of $y_t$ and the standard deviations and correlations calculated from $\exp(H_{t+1})$ respectively.

The left three panels in Figure 5 show the news impacts on the standard deviations of $y_{t+1}$ caused by the elements, $y_{1t}$ (red lines), $y_{2t}$ (blue lines) and $y_{3t}$ (black lines). The negative return on the $i$-th asset increases its own ($i$-th) future volatility, indicating the existence of leverage effects. The red lines in the middle and bottom left panels imply that the positive TOPIX return increases the future volatility of the JGB and the exchange rate returns. However, the impact of the TOPIX return on the exchange rate return volatility is smaller than that on the volatility of the JGB return. The positive shocks of the JGB return increase the future volatility of the exchange rate, while the negative shocks of the exchange rate return cause the higher future volatility of the JGB return. These results are generally consistent with those obtained with MSV model, taking account of the 95% credible intervals.

The right three panels in Figure 5 show the news impacts on the correlations among $y_{1,t+1}$, $y_{2,t+1}$ and $y_{3,t+1}$. The top right panel shows the impact on the correlation between the TOPIX and JGB returns. It is noted that the correlations are strongly affected by the exchange rate return but hardly affected by the TOPIX and the JGB returns. The black line in the middle right panel shows the impact on the correlation between the TOPIX and exchange rate returns caused by the shock of the exchange rate return. Interestingly, the sign of the correlation between the TOPIX and exchange rate returns strongly depends on the impact of the shock. More precisely, the large positive shock (greater than one) on the exchange rate return tends to produce the negative correlation between the TOPIX and exchange rate return, while the small or negative shock tends to produce the positive correlation. The sign of the correlation between the JGB and exchange rate returns also depends on the impacts of the shocks. However, we note that the impacts by shocks of the TOPIX and exchange rate returns are very small and the impacts by the JGB return shock have wide 95% intervals.

It is noted that the 95% intervals of the impact on the standard deviations and correlations looks very large and that some of them include the horizontal line (i.e. no leverage case). Thus, we calculate the posterior probability that the standard deviations and the correlations calculated from $\exp(H_{t+1})$ are larger than the posterior means of the standard
deviations and the correlations from exp(M). It means that the news impacts are larger than the posterior means of them at $y_t = 0$. Figure 6 shows the posterior probabilities of such events. The left three panels show the results for standard deviations. The posterior probability for the standard deviation of the TOPIX (exchange rate) return approaches one as the TOPIX (exchange rate) return decreases in the top (middle) left panel. The probability for the standard deviation of the JGB return also approaches one as the TOPIX return increases in the middle left panel. The right three panels show the results for correlation coefficients. The posterior probability for the correlation between the TOPIX and exchange rate returns rapidly goes to one as the exchange rate return decreases in the middle right panel.

Figure 6: Posterior probability that news impact curves are larger than the posterior mean of exp(M).

5.3 Extensions to fat-tailed error distributions and model comparison

Finally, we conduct a model comparison of the proposed MESV model with MSV models. In addition to the MESV and MSV models with normal errors, we consider extended models with fat-tailed error distribution given by

$$\varepsilon_t = \xi_{t}^{1/2}e_t, \quad e_t \sim \mathcal{N}_p(0, I_p),$$
where \( \xi_t \) is a random variable which takes positive values and independent of \( e_t \). We consider two cases: (i) multivariate Student-\( t \) error with \( \xi_t^{-1} \sim G \left( \frac{\nu}{2}, \frac{\nu}{2} \right) \) and (ii) log-Gaussian scale mixture error with \( \log \xi_t \sim \mathcal{N} \left( -\frac{\delta^2}{2}, \delta^2 \right) \). The extensions to these models are straightforward and hence we omit details of MCMC algorithms (similar specifications and MCMC sampling are also discussed in the Omori, Chib, Shephard, and Nakajima (2007) for univariate SV models, and Ishihara and Omori (2012) for MSV models). Thus, we consider the following six models:

- MSV-n model: MSV model with normal error distribution.
- MSV-t model: MSV model with multivariate Student-\( t \) error distribution.
- MSV-g model: MSV model with log-Gaussian scale mixture error distribution.
- MESV-n model: MESV model with normal error distribution.
- MESV-t model: MESV model with multivariate Student-\( t \) error distribution.
- MESV-g model: MESV model with log-Gaussian scale mixture error distribution.

We assume the prior distributions \( \nu \sim G(0.001, 0.001) \) and \( \delta^2 \sim G(1, 1) \) respectively. The estimation results for \( \nu \) and \( \delta^2 \) are summarized in Table 9. The posterior means of \( \nu \) for the MSV and MESV models are small, suggesting fat-tailed error distributions. The estimate of \( \nu \) (\( \delta^2 \)) for the MSV model is smaller (larger) than that of the MESV model, probably because the MSV model fails to capture the dynamics of time-varying correlations. Other parameter estimates are similar to those of models with normal error and hence are omitted.

We compute the DIC (deviance information criterion) for the model comparison defined by

\[
DIC = E_{\theta|Y_n}[D(\theta)] + p_D,
\]

\[
p_D = E_{\theta|Y_n}[D(\theta)] - D(E_{\theta|Y_n}[\theta]), \quad D(\theta) = -2\log f(Y_n|\theta) + C_y,
\]
where $C_y$ is a constant term which depends only on the dataset $Y_n$. Since it cancels out in all calculations that compare different models, we set $C_y = 0$ for convenience. To estimate $E_{\theta|Y_n}[D(\theta)]$, we use a sample analogue $\frac{1}{M} \sum_{m=1}^{M} D(\theta^{(m)})$, where we set $M = 100$, and $\theta^{(m)}$s are resampled from the posterior samples generated by the MCMC method. To calculate $D(E_{\theta|Y_n}[\theta])$, which equals to $D(\theta)$ evaluated at the posterior mean, we implement an auxiliary particle filter to compute the log-likelihood ordinate $\log f(Y_n|\theta)$, where we set the number of particles $I = 10,000$ for the MSV and the MESV models. We repeat this procedure ten times to obtain the numerical standard error.

</table>

Table 10 shows the averages of DIC, their standard errors, and the maximum and the minimum of DIC values computed for six competing models. The DIC values for the MESV models are much smaller than those for the MSV models, and hence the MESV models outperform the MSV models. Among MESV models, models with fat-tailed error outperform the model with normal error, and the model with multivariate-$t$ error distribution has the smallest DIC. This empirical study shows that our proposed model with multivariate-$t$ error distribution performs quite well to describe the multivariate asset returns data.

6 Conclusion

In this paper, we extend the MSV model to allow the time-varying correlations and propose an efficient MCMC algorithm using a multi-move sampler. To sample a block of state vectors, we construct a proposal density using the normal approximation via a Taylor expansion of the logarithm of the target posterior density for the MH algorithm where the expectations of Hessian matrices are derived analytically. Moreover, to calculate the log-likelihood, we describe an auxiliary particle filter. An empirical analysis is presented using
three returns of the TOPIX, the Japanese bond price index and the Yen/USD exchange rate. The correlation between returns of the TOPIX and the Japanese bond index is found to be time-varying. In contrast, the correlation between returns of the Japanese bond price index and the Yen/USD exchange rate is shown to be stable and less volatile. The positive cross leverage effects from the TOPIX on the Japanese bond price index is also found. The news impact curves for the MESV model are presented and investigated in detail. A model comparison between the MESV model with constant correlation MSV models including heavy-tailed error models is conducted. The MESV model with multivariate Student-\(t\) distributed error is found to outperform other models based on DIC.

Acknowledgment

The authors are grateful to Siddhartha Chib, Toshiaki Watanabe, Teruo Nakatsuma, and Yoshi Baba for helpful comments and discussions. This work is supported by the Research Fellowship (DC1) from the Japan Society for the Promotion of Science and the Grants-in-Aid for Scientific Research (A) 21243018 and (A) 24243031 from the Japanese Ministry of Education, Science, Sports, and Technology, and Global COE Program “Research Unit for Statistical and Empirical Analysis in Social Sciences” from the Ministry of Education, Culture, Sports, Science and Technology (MEXT) of Japan. The computational results are generated using Ox (Doornik (2006)).

Appendix

A Multi-move sampler

The logarithm of the full conditional joint density of \(\{x_t\}_{t=s}^{s+m-1}\) excluding constant terms is given by

\[
\log f(\{x_t\}_{t=s}^{s+m-1}|h_s, h_{s+m+1}, y_s, \ldots, y_{s+m}) = -\frac{1}{2} \sum_{t=s}^{s+m-1} x_t^T x_t + L, \quad (21)
\]
where

\[ L = \sum_{t=s}^{s+m} h_t - \frac{1}{2} \eta_{s+m} \Sigma_{\eta}^{-1} \eta_{s+m} I(s + m < n), \]  
\[ \eta_{s+m} = h_{s+m+1} - \mu - \Phi(h_{s+m} - \mu), \]  
\[ x_t = \Sigma_{\eta}^{-1/2}(h_{t+1} - \mu - \Phi(h_t - \mu)). \]  

Let \( \alpha_t = h_t - \mu \) and \( \hat{\alpha}_t = \hat{h}_t - \mu \) where \( \hat{h}_t \) is \( h_t \) evaluated at \( x_t = \hat{x}_t \). Consider the approximation via the second order Taylor expansion around the \( x_t = \hat{x}_t \) \((t = s, \ldots, s + m - 1)\), and replace the Hessian matrices by the negative of information matrices to obtain

\[
\log f(\{x_t\}_{t=s}^{s+m-1}|h_s, h_{s+m+1}, y_s, \ldots, y_{s+m}) 
\approx \text{const.} - \frac{1}{2} \sum_{t=s}^{s+m-1} x'_t x_t + \hat{L} 
+ \sum_{t=s+1}^{s+m} \left[ \hat{d}'_t - \frac{1}{2}(\alpha_t - \hat{\alpha}_t)' \hat{A}_t + (\alpha_{t-1} - \hat{\alpha}_{t-1})' \hat{B}_t \right] (\alpha_t - \hat{\alpha}_t)
\]

\[ = \text{const.} + \log f^*(x|\alpha_s, \alpha_{s+m+1}, y_s, \ldots, y_{s+m}), \]  

(24)

where \( \hat{d}'_t = \partial L/\partial \alpha'_t \),

\[
\hat{A}_t = -E \left[ \frac{\partial^2 L}{\partial \alpha_t \partial \alpha'_t} \right], \quad t = s + 1, \ldots, s + m, \]  
\[
\hat{B}_t = -E \left[ \frac{\partial^2 L}{\partial \alpha_t \partial \alpha'_{t-1}} \right], \quad t = s + 2, \ldots, s + m, \quad \hat{B}_{s+1} = 0, \]  

and \( \hat{d}_t, \hat{A}_t, \hat{B}_t \) are those evaluated at \( \hat{\alpha}_t \). The expectations are taken with respect to \( y_t \) given parameters and other latent variables.

A.1 Derivation of \( d_t, A_t \) and \( B_t \)

Summary of matrix differentiation

We first summarize definitions for the first and second derivatives of a matrix and some results (Magnus and Neudecker (1999), and Magnus and Abadir (2007)). Let \( F \) be a twice differentiable \( m \times p \) matrix function of an \( n \times q \) matrix \( X \). Then the first derivative (Jacobian matrix) of \( F \) at \( X \) is defined by the \( mp \times nq \) matrix

\[
D_F(X) = \frac{\partial F(X)}{\partial X} = \frac{\partial \text{vec}(F(X))}{\partial \text{vec}(X)^t},
\]
where vec(·) is a vectorizing operator, and the second derivative (Hessian matrix) of \( F \) at \( X \) is defined by the \( mnpq \times nq \) matrix

\[
HF(X) = D \left( (DF(X))^\prime \right) = \frac{\partial}{\partial(\text{vec}(X))^\prime} \text{vec} \left( \left( \frac{\partial\text{vec}(F(X))}{\partial(\text{vec}(X))^\prime} \right)^\prime \right).
\]

**Chain rule:** Let \( S \) a subset of \( \mathbb{R}^{n \times q} \), and assume that \( F : S \rightarrow \mathbb{R}^{m \times p} \) is differentiable at an interior point \( C \) of \( S \). Let \( T \) be a subset of \( \mathbb{R}^{m \times p} \) such that \( F(X) \in T \) for all \( X \in S \), and assume that \( G : T \rightarrow \mathbb{R}^{r \times s} \) is differentiable at an interior point \( B = F(C) \) of \( T \). Then the composite function \( H : S \rightarrow \mathbb{R}^{r \times s} \) defined by \( H(X) = G(F(X)) \) is differentiable at \( C \), and

\[
DH(X) = (DG(F(X)))(DF(X)) = \frac{\partial\text{vec}(G(F(X))))}{\partial(\text{vec}(X))^\prime} \frac{\partial\text{vec}(F(X))}{\partial(\text{vec}(X))^\prime}.
\]

When \( q = 1 \), \( x \in \mathbb{R}^{n \times 1} \), \( f : \mathbb{R}^{n \times 1} \rightarrow \mathbb{R}^{m \times p} \), \( g : \mathbb{R}^{m \times p} \rightarrow \mathbb{R}^{r \times s} \),

\[
\frac{\partial g(f(x))}{\partial x'} = \frac{\partial\text{vec}(g(f(x))))}{\partial(\text{vec}(x))^\prime} \frac{\partial\text{vec}(f(x))}{\partial(\text{vec}(x))^\prime}.
\]

**Product rule:** Let \( S \) a subset of \( \mathbb{R}^{n \times q} \), and assume that \( F : S \rightarrow \mathbb{R}^{m \times p} \) and \( G : S \rightarrow \mathbb{R}^{p \times r} \) are differentiable at an interior point \( C \) of \( S \). Then

\[
\frac{\partial\text{vec}(FG)}{\partial(\text{vec}(X))^\prime} = (G' \otimes I_m) \frac{\partial\text{vec}(F)}{\partial(\text{vec}(X))^\prime} + (I_r \otimes F) \frac{\partial\text{vec}(G)}{\partial(\text{vec}(X))^\prime}.
\]

**Derivation of \( d_t \)**

Let \( F_t = -\frac{1}{2}H_t \) and \( z_t = \exp(F_t)y_t \). The logarithm of the conditional probability density of \( y_t \) given \( h_t \) excluding the constant term is

\[
l_t = -\frac{1}{2}\text{tr}(H_t) - \frac{1}{2}(z_t - m_t)'S_t^{-1}(z_t - m_t),
\]

where \( E[z_t] = m_t = \Sigma_{\eta \eta}^{-1} (\alpha_{t+1} - \Phi \alpha_t)I(t < n) \) and \( E[z_t z_t'] = S_t + m_t m_t' \) with \( S_t = I_p - \Sigma_{\eta \eta} \Sigma_{\eta \eta}^{-1} \Sigma_{\eta t}I(t < n) \). Further, let \( D_p \) denote a \( p^2 \times q \) duplication matrix (whose elements are 0 or 1) such that \( \text{vec}(A) = D_p\text{vech}(A) \) for a symmetric matrix \( A \). Then

\[
\frac{\partial\text{tr}(H_t)}{\partial \alpha_t} = \frac{\partial\text{tr}(H_t)}{\partial \text{vec}(H_t)^\prime} = \text{vec}(I_p)'D_p = \text{vech}(I_p)',
\]

\[
\frac{\partial m_t}{\partial \alpha_t} = -\Sigma_{\eta \eta} \Sigma_{\eta \eta}^{-1} \Phi I(t < n),
\]

\[
\frac{\partial m_{t-1}}{\partial \alpha_t} = \Sigma_{\eta \eta} \Sigma_{\eta \eta}^{-1} I(t > 1),
\]

32
where we used the chain rule and \( D_p' \text{vec}(A) = \text{vech}(A + A' - (A \odot I_p)) \) for a \( p \times p \) matrix \( A \) in (30) (e.g. Magnus and Neudecker (1999), Magnus (1988)). Further, define

\[
V_t = \sum_{i=1}^{\infty} \sum_{j=1}^{i} \left( F_t^{i-j} \otimes F_t^{j-1} \right),
\]

using the product rule and let \( Q_t = \{ \exp(-F_t) \otimes I_p \} V_t \). Noting that \( z_t = (y_t' \otimes I_p) \text{vec}(\exp(F_t)) \),

\[
\frac{\partial z_t}{\partial \alpha_t'} = -\frac{1}{2} (y_t' \otimes I_p) V_t \frac{\partial \text{vec}(H_t)}{\partial h_t'}.
\]

Using (30) – (33) and \( \partial x' Ax/\partial x' = 2x' A \) for a \( p \times p \) symmetric matrix \( A \) and a \( p \times 1 \) vector \( x \), we obtain

\[
d_t = \left[ \frac{\partial l_t}{\partial \alpha_t'} \right]' + \Phi \Sigma_{\eta \eta}^{-1} (\alpha_{t+1} - \Phi \alpha_t) I (t = s + m < n)
\]

\[
= -\frac{1}{2} \text{vech}(I_p) + \left\{ \frac{1}{2} D_p' Q_t'(z_t \otimes I_p) - \Phi \Sigma_{\eta \eta}^{-1} \Sigma_{\eta \epsilon} I (t < n) \right\} S_t^{-1} (z_t - m_t)
\]

\[
+ \Sigma_{\eta \eta}^{-1} \Sigma_{\eta \epsilon} S_{t-1}^{-1} (z_{t-1} - m_{t-1}) I (t > 1) + \Phi \Sigma_{\eta \eta}^{-1} (\alpha_{t+1} - \Phi \alpha_t) I (t = s + m < n). \quad (34)
\]

Although \( Q_t \) involves an infinite series of matrices, its computation is easy as shown in Appendix A.2.

**Derivation of \( A_t \)**

By (31)–(34) and \( Q_t'(z_t \otimes I_p) = V_t (y_t \otimes I_p) \),

\[
A_t = -\frac{1}{2} D_p' E \left[ \frac{\partial V_t (y_t \otimes I_p) S_t^{-1} (z_t - m_t)}{\partial \alpha_t'} \right] - \frac{1}{2} \Phi N_t'
\]

\[
+ \Phi M_t \Phi + M_{t-1} + \Phi \Sigma_{\eta \eta}^{-1} \Phi I (t = s + m < n), \quad (35)
\]

where

\[
M_t = \Sigma_{\eta \eta}^{-1} \Sigma_{\eta \epsilon} S_{t-1}^{-1} \Sigma_{\epsilon \eta} \Sigma_{\eta \eta}^{-1} I (1 \leq t < n), \quad (36)
\]

\[
N_t = D_p' Q_t' (m_t \otimes I_p) S_{t-1}^{-1} \Sigma_{\epsilon \eta} \Sigma_{\eta \eta}^{-1}. \quad (37)
\]
Using a product rule and $\partial \text{vec}(F_t)/\partial \alpha_t' = -\frac{1}{2} D_p$, we obtain

$$
\frac{\partial V_t(y_t \otimes I_p)S_t^{-1}(z_t - m_t)}{\partial \alpha_t'} = -\frac{1}{2} \left\{ (z_t - m_t)'S_t^{-1} \otimes I_p^2 \right\} \left\{ (y_t' \otimes I_p) \otimes I_p^2 \right\} W_t D_p + V_t(y_t \otimes I_p)S_t^{-1} \frac{\partial (z_t - m_t)}{\partial \alpha'_t},
$$

where $W_t = \partial \text{vec}(V_t)/\partial \text{vec}(F_t)'$. Since

$$
E \left[ \left\{ (z_t - m_t)'S_t^{-1} \otimes I_p^2 \right\} \left\{ (y_t' \otimes I_p) \otimes I_p^2 \right\} \right] = E \left[ (z_t - m_t)'S_t^{-1}(y_t' \otimes I_p) \otimes I_p^2 \right] = E \left[ \text{vec}(S_t^{-1}(z_t - m_t)y_t') \otimes I_p^2 \right] = \text{vec}(\exp(-F_t))' \otimes I_p^2,
$$

and

$$
E \left[ V_t(y_t \otimes I_p)S_t^{-1} \frac{\partial (z_t - m_t)}{\partial \alpha'_t} \right] = -\frac{1}{2} Q'_t E \left[ (z_t \otimes I_p)S_t^{-1}(z_t' \otimes I_p) \right] Q_t D_p + Q'_t(m_t \otimes I_p)S_t^{-1} \Sigma_{\epsilon \eta} \Sigma_{\eta \eta}^{-1} \Phi
$$

$$
= -\frac{1}{2} Q'_t E \left[ (z_t z_t') \otimes S_t^{-1} \right] Q_t D_p + Q'_t(m_t \otimes I_p)S_t^{-1} \Sigma_{\epsilon \eta} \Sigma_{\eta \eta}^{-1} \Phi
$$

$$
= -\frac{1}{2} Q'_t \left\{ (S_t + m_t m_t') \otimes S_t^{-1} \right\} Q_t D_p + Q'_t(m_t \otimes I_p)S_t^{-1} \Sigma_{\epsilon \eta} \Sigma_{\eta \eta}^{-1} \Phi,
$$

Equation (35) reduces to

$$
A_t = \frac{1}{4} D'_p \left[ P_t + Q'_t \left\{ (S_t + m_t m_t') \otimes S_t^{-1} \right\} Q_t \right] D_p - \frac{1}{2} (N_t \Phi + \Phi N_t')
$$

$$
+ \Phi M_t \Phi + M_{t-1} + \Phi \Sigma_{\eta \eta}^{-1} \Phi I(t = s + m < n),
$$

(38)

where $D'_p P_t = D'_p \left\{ \text{vec}(\exp(-F_t))' \otimes I_p^2 \right\} W_t$. The computation of $P_t$ as well as $Q_t$ is discussed in Appendix A.2.

**Derivation of $B_t$**

By (31), (33) and (34),

$$
B_t = -\Sigma_{\eta \eta}^{-1} \Sigma_{\eta \xi} S_{t-1}^{-1} E \left[ \frac{\partial (z_{t-1} - m_{t-1})}{\partial \alpha'_{t-1}} \right] = \frac{1}{2} N'_{t-1} - M_{t-1} \Phi, \quad t = 2, \ldots, n.
$$

(39)
A.2 Computation of \( P_t \) and \( Q_t \)

(1) \( Q_t \)

Since \( F_t \) is a symmetric matrix, there exists a \( p \times p \) orthogonal matrix \( U_t \) such that

\[
U_t' F_t U_t = \Lambda_t,
\]

where \( \Lambda_t = \text{diag}(\lambda_{1t}, \lambda_{2t}, \ldots, \lambda_{pt}) \) and \( \lambda_{1t} \geq \lambda_{2t} \geq \ldots \geq \lambda_{pt} \) are the ordered eigenvalues of \( F_t \). Then

\[
Q_t = \left\{ \exp(-F_t) \otimes I_p \right\} \sum_{i=1}^{\infty} \frac{1}{i!} \sum_{j=1}^{i} \left[ F_i^{i-j} \otimes F_i^{j-1} \right],
\]

\[
= \sum_{i=1}^{\infty} \frac{1}{i!} \sum_{j=1}^{i} \left[ \exp(-F_t) F_i^{i-j} \otimes F_i^{j-1} \right],
\]

\[
= (U_t \otimes U_t) \left[ \sum_{i=1}^{\infty} \frac{1}{i!} \sum_{j=1}^{i} \left\{ \exp(-\Lambda_t) \Lambda_i^{i-j} \otimes \Lambda_i^{j-1} \right\} \right] (U_t' \otimes U_t'). \tag{40}
\]

The second factor in (40) is a diagonal matrix with its \((k,k)\)-th element given by

\[
\sum_{i=1}^{\infty} \frac{1}{i!} \sum_{j=1}^{i} \exp(-\lambda_{at}) \lambda_i^{i-j} \lambda_j^{j-1} = \begin{cases} 1, & \text{if } \lambda_{at} = \lambda_{bt}, \\ \frac{\exp(\lambda_{at} - \lambda_{bt}) - 1}{\lambda_{bt} - \lambda_{at}}, & \text{if } \lambda_{at} \neq \lambda_{bt}, \end{cases}
\]

where \( a = [(k-1)/p] + 1 \) and \( b = k - p[(k-1)/p] \), and \([x]\) denotes the integer part of \(x\). Note that \( \lambda_{at} = \lambda_{bt} \) for \( k = (i-1)p + i \ (i = 1, \ldots, p) \).

(2) \( P_t \)

Let \( K_{mn} \) denote a \( mn \times mn \) 0-1 matrix called a commutation matrix such that \( \text{vec}(A') = K_{mn} \text{vec}(A) \) holds for a \( m \times n \) matrix \( A \) (see Chapter 3 of Magnus and Neudecker (1999)). Using

\[
\frac{\partial \text{vec}(A \otimes B)}{\partial \text{vec}(A')} = (I_n \otimes K_{qm} \otimes I_p)(I_{mn} \otimes \text{vec}(B)),
\]

\[
\frac{\partial \text{vec}(A \otimes B)}{\partial \text{vec}(B')} = (I_n \otimes K_{qm} \otimes I_p)(\text{vec}(A) \otimes Ipq),
\]

35
where \( A, B, X \) are \( m \times n, p \times q, n \times p \) matrices respectively, we compute

\[
W_t = \frac{\partial \text{vec}(V_t)}{\partial \text{vec}(F_t)^t} = \sum_{i=2}^{\infty} \frac{1}{i!} \sum_{j=1}^{i} \frac{\partial \text{vec}(F_t^{i-j} \otimes F_t^{j-1})}{\partial \text{vec}(F_t)^t} \\
= \sum_{i=2}^{\infty} \frac{1}{i} (I_p \otimes K_{pp} \otimes I_p) \left\{ \sum_{j=1}^{i-1} (I_p \otimes \text{vec}(F_t^{j-1})) \frac{\partial \text{vec}(F_t^{i-j})}{\partial \text{vec}(F_t)^t} \right\} \\
+ \sum_{j=2}^{i} (\text{vec}(F_t^{i-j}) \otimes I_p) \frac{\partial \text{vec}(F_t^{j-1})}{\partial \text{vec}(F_t)^t} \right\},
\]

and, using the product rule,

\[
\frac{\partial \text{vec}(F_t^k)}{\partial \text{vec}(F_t)^t} = \sum_{m=1}^{k} F_t^{k-m} \otimes F_t^{m-1}.
\]

Note that

\[
\{ \text{vec}(\exp(-F_t)) \otimes I_p^2 \} \{ I_p \otimes K_{pp} \otimes I_p \} \left\{ I_p \otimes \text{vec}(F_t^{j-1}) \right\} \frac{\partial \text{vec}(F_t^{i-j})}{\partial \text{vec}(F_t)^t} \\
= K_{pp} (F_t^{j-1} \exp(-F_t) \otimes I_p) \frac{\partial \text{vec}(F_t^{i-j})}{\partial \text{vec}(F_t)^t} = K_{pp} \sum_{h=1}^{i-1} F_t^{j-1} \exp(-F_t) F_t^{i-j-h} \otimes F_t^{h-1},
\]

and

\[
\{ \text{vec}(\exp(-F_t)) \otimes I_p^2 \} \{ I_p \otimes K_{pp} \otimes I_p \} \left\{ \text{vec}(F_t^{i-j}) \otimes I_p^2 \right\} \frac{\partial \text{vec}(F_t^{j-1})}{\partial \text{vec}(F_t)^t} \\
= \left\{ F_t^{i-j} \exp(-F_t) \otimes I_p \right\} \frac{\partial \text{vec}(F_t^{j-1})}{\partial \text{vec}(F_t)^t} = \sum_{h=1}^{i-1} F_t^{i-j} \exp(-F_t) F_t^{i-j-h} \otimes F_t^{h-1},
\]

by using

\[
K_{nn}(BA \otimes I_n) = (\text{vec}(A)^t \otimes I_n^2)(I_n \otimes K_{nn} \otimes I_n)(I_n^2 \otimes \text{vec}(B)), \quad (41) \\
(BA^t \otimes I_n) = (\text{vec}(A)^t \otimes I_n^2)(I_n \otimes K_{nn} \otimes I_n)(\text{vec}(B) \otimes I_n^2), \quad (42)
\]

36
where \( A \), \( B \) are \( m \times n \), \( p \times q \) matrices (e.g. Theorem 4.4 of Rogers (1980) on p. 23). Thus, using \( D_p'K_{pp} = D_p' \),

\[
D_p'P_t = D_p' \left\{ \text{vec}(\exp(-F_t))' \otimes I_{p^2} \right\} W_t \\
= D_p' \sum_{i=2}^{\infty} \frac{1}{i!} \left( \sum_{j=1}^{i-2} \sum_{h=1}^{j} \exp(-F_t)F_{i-h-1} \otimes F_{j-1}^{-1} + \sum_{j=2}^{i-1} \sum_{h=1}^{j} \exp(-F_t)F_{i-j-1} \otimes F_{h}^{-1} \right) \\
= 2D_p' \sum_{i=2}^{\infty} \frac{1}{i!} \left( \sum_{j=1}^{i-2} \sum_{h=1}^{j} \exp(-F_t)F_{i-h-1} \otimes F_{j-1}^{-1} \right) \\
= 2D_p' \sum_{i=2}^{\infty} \frac{1}{i!} \sum_{j=1}^{i-1} (i-j) \exp(-F_t)F_{i-j-1} \otimes F_{j-1}^{-1} ,
\]

and we obtain

\[
P_t = 2 \sum_{i=2}^{\infty} \frac{1}{i!} \sum_{j=1}^{i-1} (i-j) \exp(-F_t)F_{i-j-1} \otimes F_{j-1}^{-1} \\
= (U_t \otimes U_t) \left[ 2 \sum_{i=2}^{\infty} \frac{1}{i!} \sum_{j=1}^{i-1} (i-j) \left\{ \exp(-\Lambda_t)\Lambda_{i-j-1}^{i-j-1} \otimes \Lambda_{j-1}^{j-1} \right\} \right] (U_t' \otimes U_t') . \tag{43}
\]

The second factor in (43) is a diagonal matrix with its \((k,k)\)-th element given by

\[
2 \sum_{i=2}^{\infty} \frac{1}{i!} \sum_{j=1}^{i-1} (i-j) \exp(-\lambda_{at})\lambda_{at}^{i-j} \lambda_{bt}^{j-1} = \begin{cases} 1, & \text{if } \lambda_{at} = \lambda_{bt}, \\ \frac{2(\exp(\lambda_{at})-1-\lambda_{at})}{(\lambda_{at}-\lambda_{bt})^2} & \text{if } \lambda_{at} \neq \lambda_{bt}, \end{cases}
\]

where \( a = \lfloor (k-1)/p \rfloor + 1 \) and \( b = k - p\lfloor (k-1)/p \rfloor \).
